+ more.....

EuroCold Lab

Despite the glaciers are distributed at all the Latitudes, ice core drilling will not done anywhere.

Glaciers are one of the best archives of atmospheric data, but the fragility of its environment can present troubles on data sequences.

Summer melting or winter wind erosion can reduce or cancel the informations stored in the ice.

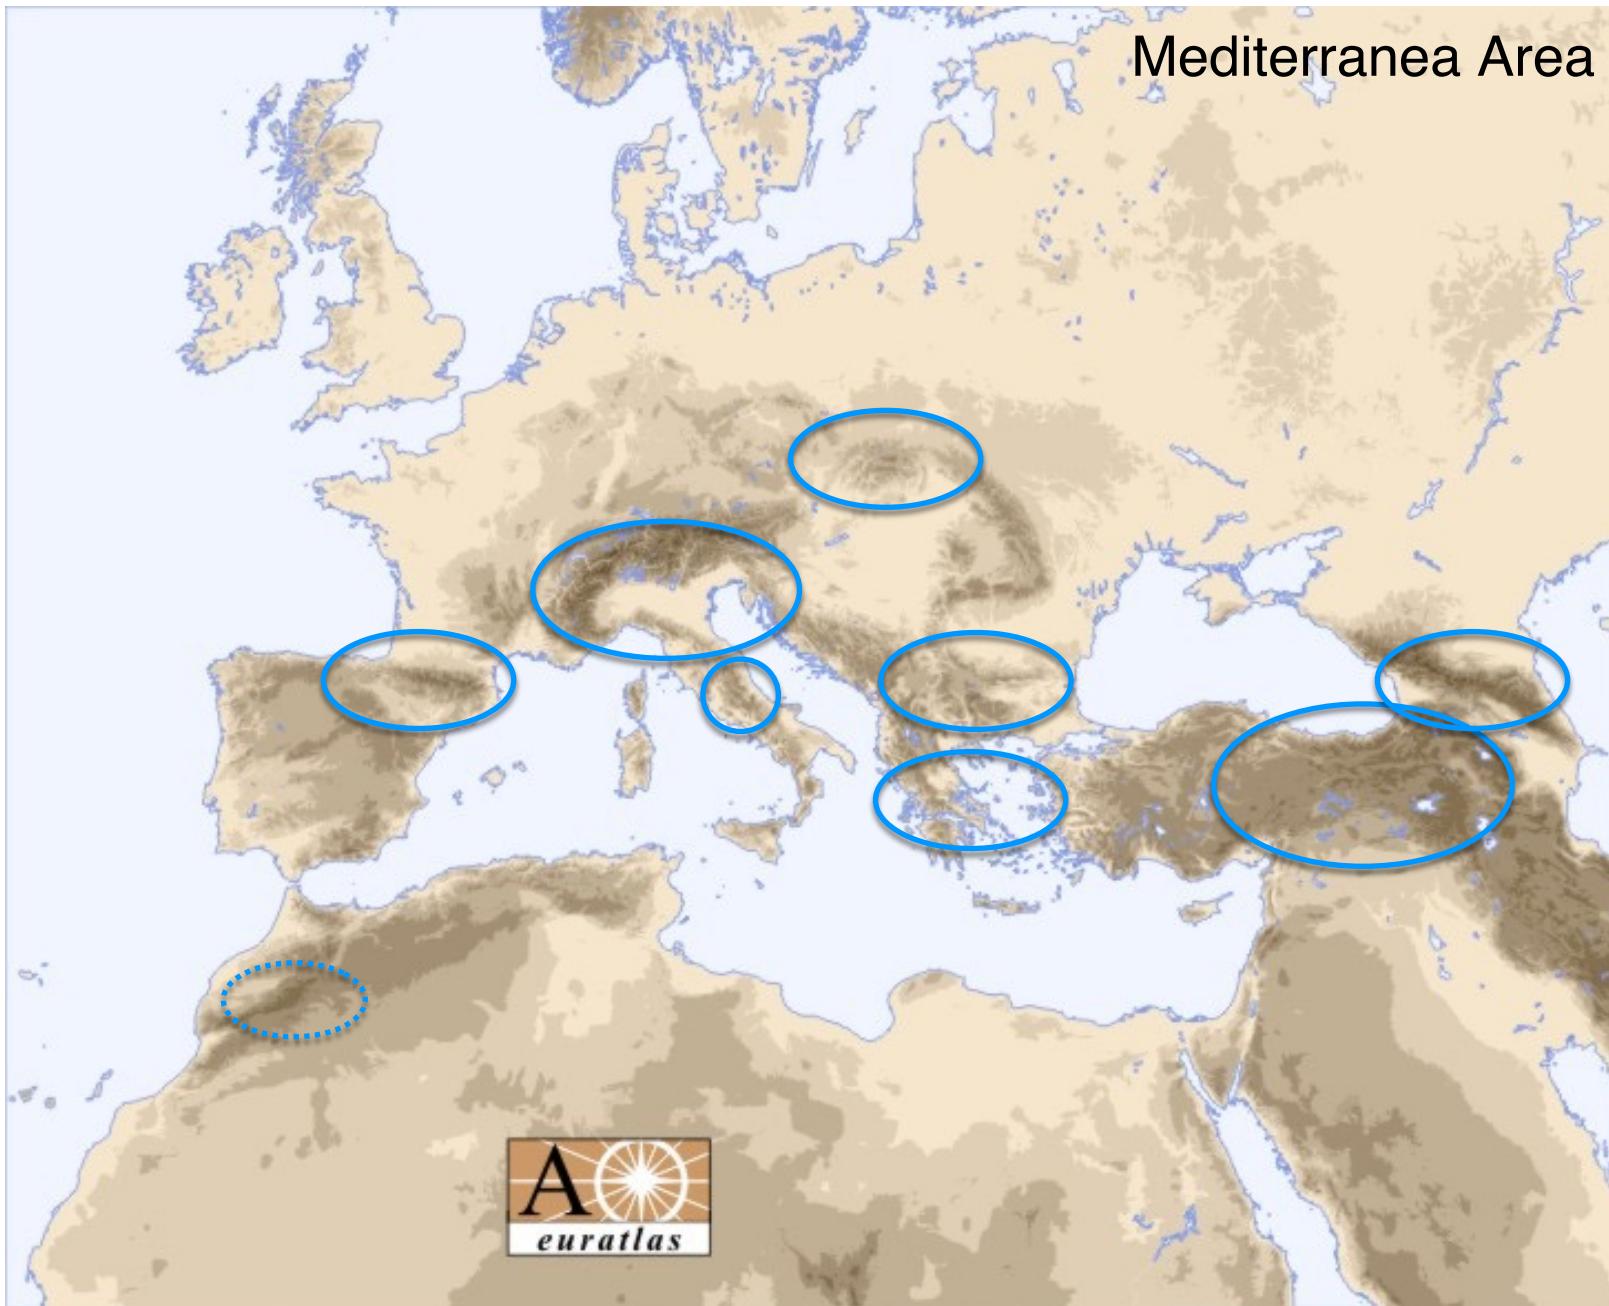

Only glaciers (or part of them) in cold conditions, with T° below 0°C , can be useful for this kind of studies, normally located at high altitude inside the mountain chains.

In the Alpine region, with few exceptions, 3800-4000 m as seem to be a limit for this kind of the work. In the Himalaya-Karakorum systems, need to reach 5-6000 m asl or more.

IDB - Ice Core Database v 1.0

Introduction

In this page are presented two useful tools to search in quickly and efficient way ice core data. In the page is possible find:

- a form built with drop-down menus, this is the core of the page, from there you can concretely download the data;
- a webGIS that can be used to localize and get information about name and dataprovider of the ice cores.

How to

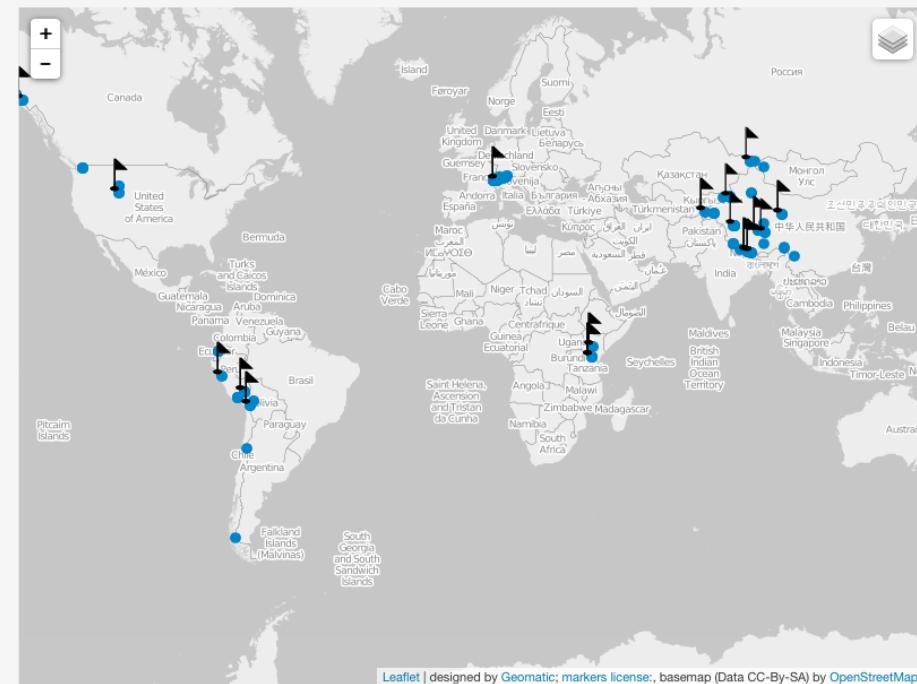

Three drop-down menu has been built to retrieve chemical and physical ice cores data characterizations. It is possible select an ice core name, a dataprovider or a parameter name. You can start your research with any of these three variables. When a variable is selected, automatically the other two drop-down menu will be related with this choice. The dowloading file format is CSV with comma separated field. To generate it just press the download button. You can download data selecting even only one of the three variables (e.g.selecting 'maggi v.' as dataprovider, you can directly download all ice cores data related to him.)

select icecore name ...

select dataprovider name ...

select parameter name ...

WebGIS

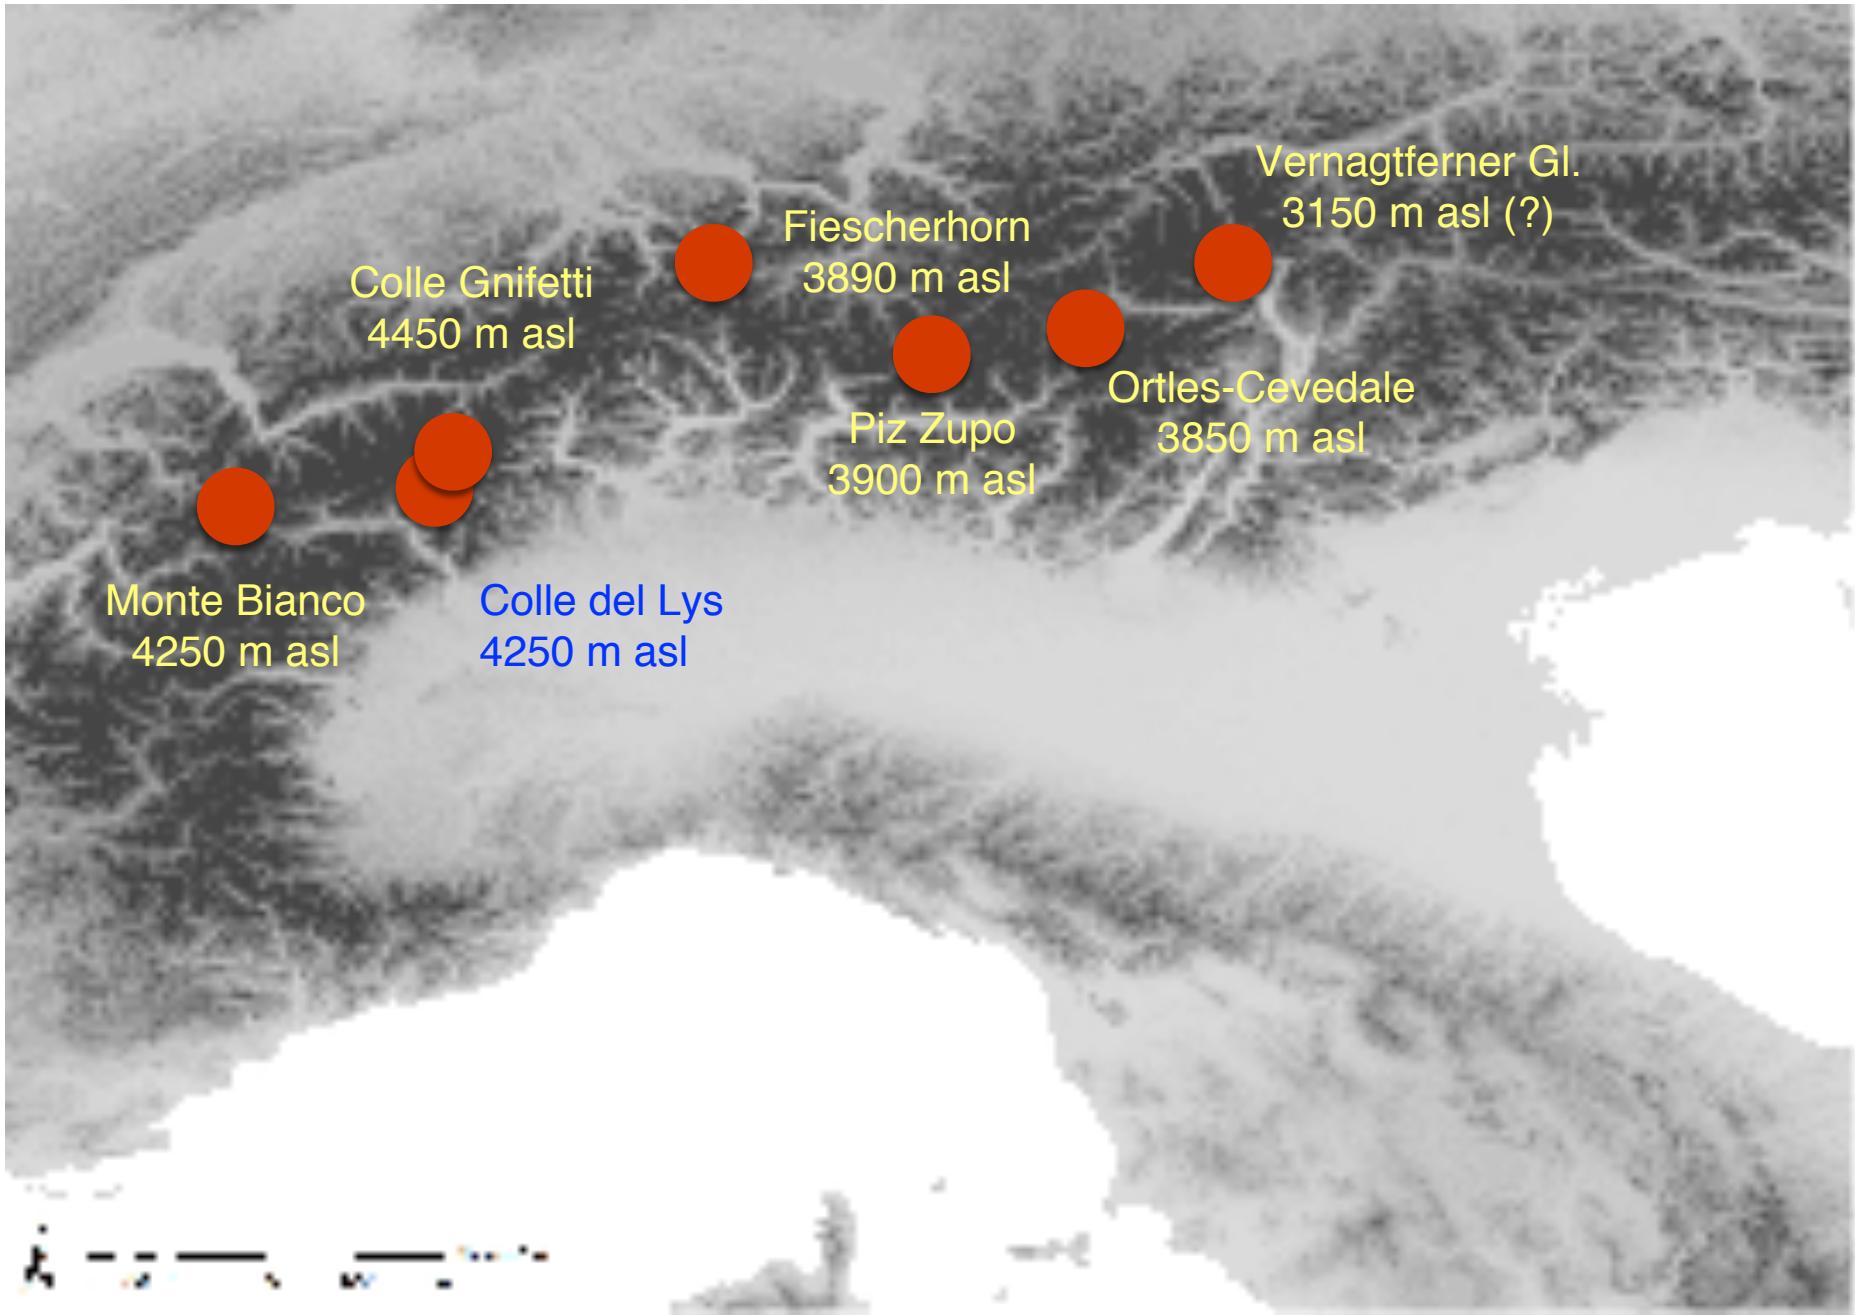

EuroCold Lab

The ice core distribution around the world cover all the most high mountain chains , as Rockies, Ande, Himalaya-Karakorum, Alps and African equatorial glaciers.

In the frame of NEXTDATA Project, a open database of all the known ice core were build up.

More than 270 ice core was drilled in more than 70 sites worldwide.

The Alpine consistency
7 Sites for 44 ice cores

The ice core records for the Alpine area cover the entire Holocene and part of Younger Dryas (around 13.000 BC). Most of the records span the last centuries, with special emphasis the last 70-100 years.

Strong drop in the last decade.

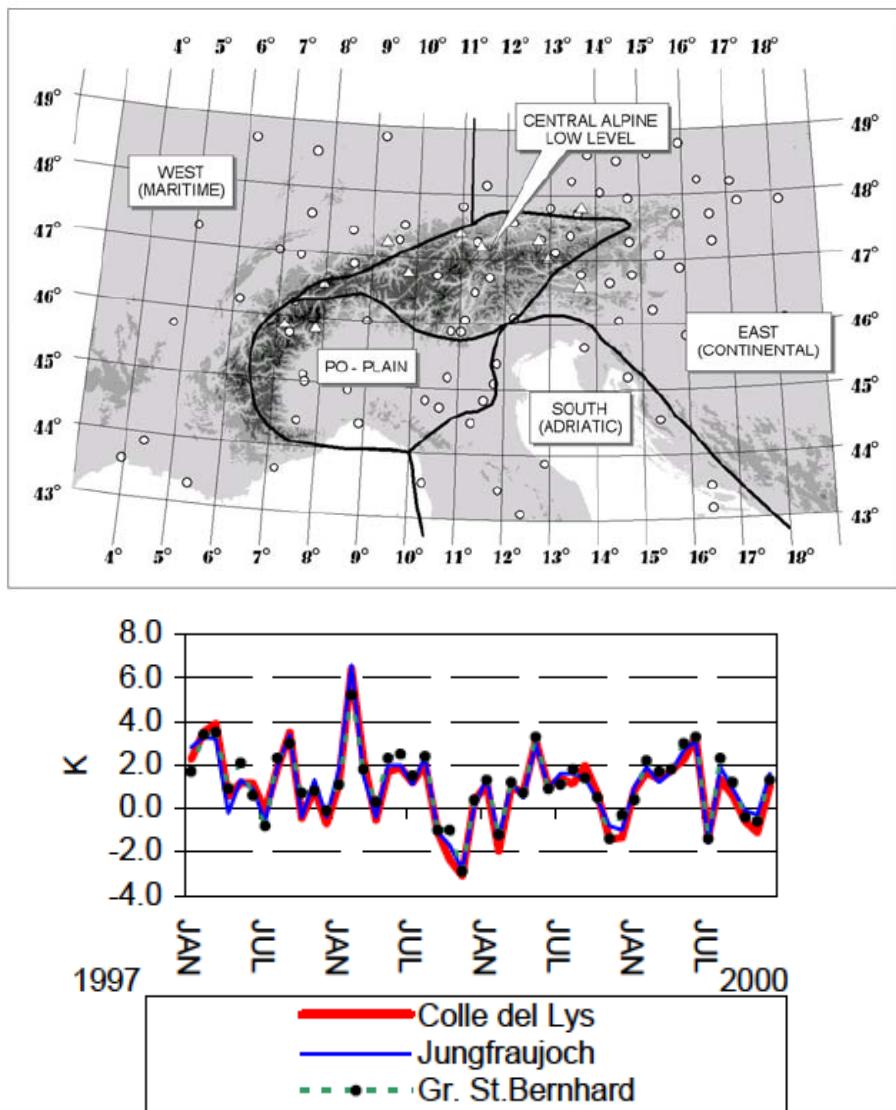

The decrease of the length in time, increase the resolution, until the seasonality for the shorter records.

cm (depth)

The high resolution permit to recognize seasonality also in other records different to the stable isotopes. As the atmospheric dust, where high concentration during the spring-to-summer periods are in opposite respect the low concentration during fall-to-winter. Or human product as ammonia or sulfates

Some remarks

The dust concentration (both, microparticles and Calcium records), mainly related to the transport from North Africa seem to have a general features along the Alpine area.

The last 2 decades seem to be related to high concentration, despite the beginning-to-meddle of XX century the level seem to be lower.

In reality exists some difficult to interpret these data, because the transport from North Africa across the Mediterranean use different baric mechanisms.
