Scientific Report for the reference period 1/01/2018-30/06/2018

Deliverable D1.5.D (December 2018)

**Database of the geochronological and geochemical information from tephra layers
documented in the marine sediment cores from the analysed key sites and from literature data
Resp. Fabrizio Lirer, CNR-ISMAR**

Alberico Ines⁽¹⁾, Insinga Donatella Domenica⁽¹⁾, Petrosino Paola⁽²⁾,

- 1) Istituto di Scienze Marine (ISMAR)– Consiglio Nazionale delle Ricerche, Calata Porta di Massa, Interno Porto di Napoli, 80133, Napoli, Italia
- 2) DiSTAR — Dipartimento di Scienze della Terra, dell'Ambiente e delle Risorse, Università degli Studi di Napoli Federico II, Largo S. Marcellino 10, 80138 Napoli, Italy

Since tephtras are the result of “instantaneous” events in terms of geological times, they are considered powerful “isochronous time-lines” to link archives from different settings and, if a numerical age can be attributed, they become the most suitable proxy used for the age modelling of sedimentary records. Along with the contribution to the paleoenvironmental and paleoclimate research, tephtras can also provide a detailed record of volcanic activity and recurrence rates during the Quaternary.

Dealing with widespread markers, which represent powerful isochrones, different archives can be linked throughout the Mediterranean. The use of such correlating tools allows to bypass issues from any possible leads or lags of climate changes evidenced by other proxies (e.g. foraminiferal

distribution, oxygen isotope) at both regional and Mediterranean scales, provided the tephra correlation is correct.

This is particularly true when dealing with tephras interbedded within deep sea and lacustrine successions (characterized by continuous records) with no or little sedimentary disturbances. In this case, even thin tephras associated with small, local eruptions or large distal eruptions can be preserved.

WDB-Paleo, containing data on about 6000 marine sediment cores (Alberico et al., 2017). It was upgraded until 2019 according to the newly published papers and particular attention was posed on the implementation of new marine tephra entities recording tephra information (fig. 1).

Tephra samples were classified as tephra or cryptotephra and for each one the eruption name, source, composition, age, references and correlation with other equivalents were registered (see appendix A).

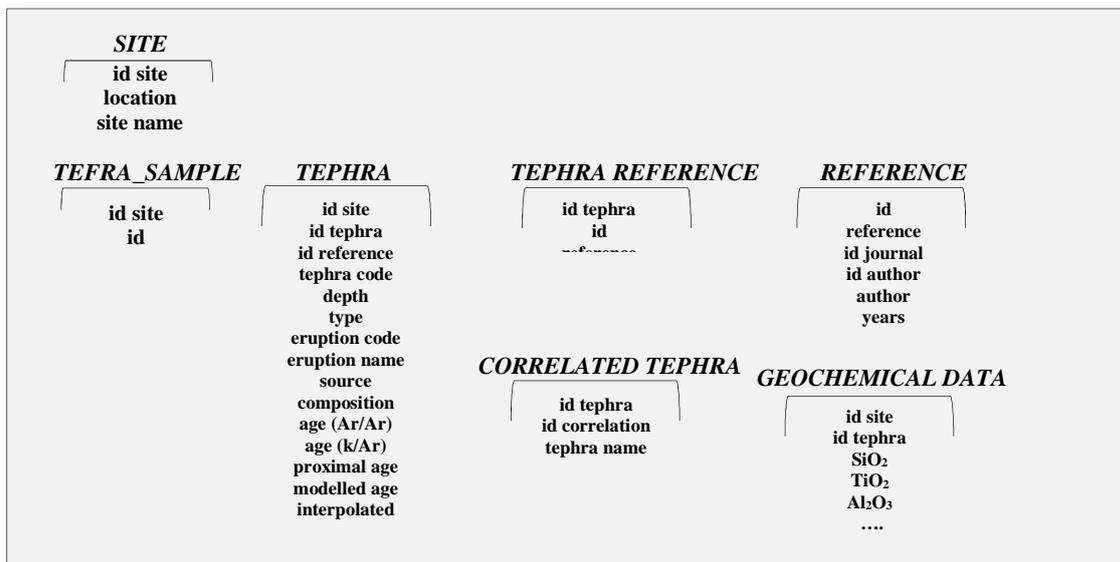

FIG. 1 – Entities recording data on tephra and cryptotephra.

In the whole Mediterranean Sea, tephra and cryptotephra have been analyzed in about 198 sediment cores for different purposes and about 1000 tephra layers are recorded into database.

This latter takes advantage of a link with a Geographical Information System (GIS) to draw for both geographical area and specific time interval the distribution of cores for which tephra layers were published.

As an example, Figures 2A, B and 3 show the distribution of the tephra e criptotephra related to the protohistoric interplinian activity, which occurred at Somma-Vesuvius between the Avellino (ca 3.9 cal ka, Sevink et al., 2011) and the 79 CE explosive events. During this time span a complex sequence of pyroclastic products was deposited and related at least to six main explosive events (AP1 to AP6; Andronico and Cioni, 2002). This activity has been described in detail at proximal sites, and more recently in the marine settings due to enhanced cryptotephra studies.

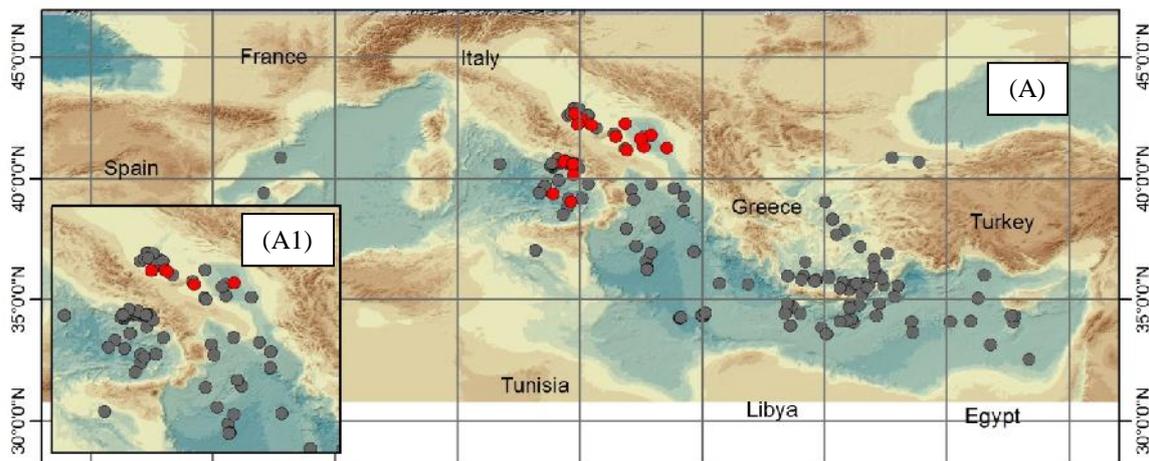

Fig.2 – Tephra outcomes from the data stored in WDB-Paleo (gray dots). (A) Occurrence of all AP related tephras (red dots) and (A1) occurrence of AP2 related tephra (ca. 3.5 cal ka in Santacroce et al., 2008- A1)

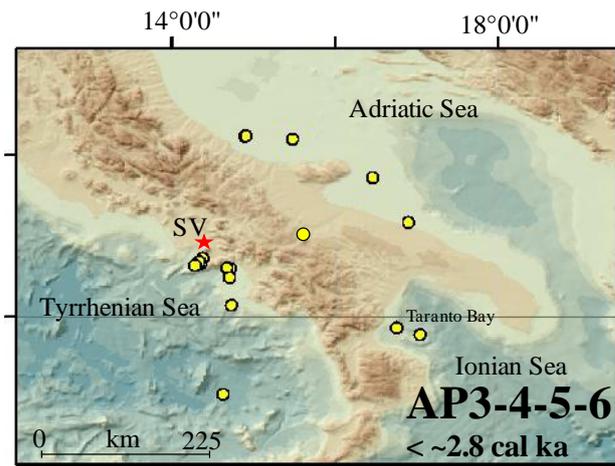

Fig.3 – Ash dispersal for the AP3-6 (< ca 2.8 cal ka; Rolandi et al., 1998) related tephra erupted during the interplinian activity of Somma-Vesuvius soon after the Avellino major event.
